

Where the runs end up on the landscape — predator environment

$f(\theta)$ is read off the plane at the projected centroid, not the run's own recorded fitness: the plane holds 62–69% of each run's motion, so about a third of the journey is perpendicular to the page. Each path is read on the pass it ran under — evolution on RL off, learning on RL on — so the dashed curves break wherever a cell was masked for short RL-on coverage. The plane is anchored on the EVOLUTION run, so the learning path is a guest on it and its curve understates that run: read the learning runs' own final fitness from endpoints.csv, not off this axis.
